

Striped Amber (no aka)

Most Commonly Used Name: Striped Amber

Mode of Genetic Inheritance: Recessive

Morph Type: Mutation compound (Stripe + Caramel + Hypo A)

This compound recessive morph results from combining the three recessive color mutations; Stripe, Caramel and Hypo A. As most pattern mutations in corns do, Stripe has the visual impact on this triple mutant of brightening the overall yellow coloration.

What to expect:

Hatchlings are generally brown to brownish gold, but lighten with age, rendering a beautiful pale gold to bright yellow overall coloration. Never expect to see black on Striped Ambers, as all markings are darkened versions of the basal ground coloration. Adults are usually bright yellow, with tan to brown longitudinal markings.

Important Note:

The advertising images on our web site are representations of the average adult example of each morph. These images are not renderings of the actual animals being offered, (except for uniquely offered snakes found in the SURPLUS section of this web site). We do not provide pictures of individual hatchling snakes for sale, nor do we recommend that you ever choose a new pet based on an image of its neonatal form. Corns change so dramatically from hatchling to adult, they will NEVER have the same colors or contrasts throughout maturity. While most of the snakes we produce will mature to resemble the featured adult image(s) on our web site, unlike manufactured products that are respectively clones of each other, the nature of polygenic variation results in each animal being similar but not identical to others of its morph. The snake we select for you may not mature to be identical to the pictured examples, but will be chosen based on our experience of observing which neonates will mature to properly represent their respective morph. We take this responsibility very seriously, and therefore publish the guarantee that we will exchange your SMR snake if it does not mature to be like our advertised examples.
