

Caramel Motley (no aka)

Most Commonly Used Name: Caramel Motley

Mode of Genetic Inheritance: Recessive

Morph Type: Mutation Compound (Caramel & Motley)

Eye Color: Black pupil & *body ground colored* iris

This compound morph results from combining the color mutation, Caramel with the pattern mutation Motley. As Motley does in genetic union with most other color mutations of corns, the aggregate appearance of this compound morph is certainly improved. The mechanics of both base mutations are explained on the hyperlinked pages for Caramel and Motley.

What to expect:

Motley pattern is typically variable and color is also variable. Colors of hatchling can vary from gold to brown to a greenish hue and all shades of those colors. Some even resemble pale versions of anery mutants, but as adults all of ours mature to be shades of gold or brown.

Important Note:

These images are not renderings of the actual animals being offered, (except for uniquely offered snakes found in the SURPLUS section of this web site). We do not provide pictures of individual hatchling snakes for sale, nor do we recommend that you ever choose a new pet based on an image of its neonatal form. Corns change so dramatically from hatchling to adult, they will NEVER have the same colors or contrasts throughout maturity. While most of the snakes we produce will mature to resemble the featured adult image(s) on our web site, unlike manufactured products that are respectively clones of each other, the nature of polygenic variation results in each animal being similar but not identical to others of its morph. The snake we select for you may not mature to be identical to the pictured examples, but will be chosen based on our experience of observing which neonates will mature to properly represent their respective morph. We take this responsibility very seriously, and therefore publish the guarantee that we will exchange your SMR snake if it does not mature to be like our advertised examples.
