

RedCoat Lava (no AKA)

Most Commonly Used Name: RedCoat Lava

Mode of Genetic Inheritance: Recessive

Morph Type: Recessive Mutation Compounds, Lava and RedCoat

Eye Color: Usually reddish-black pupil with orange/brown iris

The simple recessive **mutation**, Lava was discovered by Joe Pierce in the 1990s and was originally called Translucent or Transparent Hypo. They reportedly originated from a wild-caught corn snake that was collected in the area of the Southeastern United States where the famous Okeetee corns are collected in South Carolina. Adding Joe's RedCoat mutation (recessive to wild-type) and you get some scalding colorful results.

#### Important Note:

These images are not renderings of the actual animals being offered, (except for uniquely offered snakes found in the SURPLUS section of this web site). We do not provide pictures of individual hatchling snakes for sale, nor do we recommend that you ever choose a new pet based on an image of its neonatal form. Corns change so dramatically from hatchling to adult, they will NEVER have the same colors or contrasts throughout maturity. While most of the snakes we produce will mature to resemble the featured adult image(s) on our web site, unlike manufactured products that are respectively clones of each other, the nature of polygenic variation results in each animal being similar but not identical to others of its morph. The snake we select for you may not mature to be identical to the pictured examples, but will be chosen based on our experience of observing which neonates will mature to properly represent their respective morph. We take this responsibility very seriously, and therefore publish the guarantee that we will exchange your SMR snake if it does not mature to be like our advertised examples.
