

Show & Tell

After three impatient DAYs of waiting while this gem resorbed her yolk, she's finally being photogenic for me at the time of these photographs, FriDAY, March 2nd. NO, this is not the one I showed you yesterDAY, but this one could also be a Sun Motley. I'm sure enough about the color, but pattern is so far not easily discerned? Upon first blush, a generally feature-less corn snake, I cannot wait to see her mature phenotype. I say "feature-less" because she appears to lack all exhibition of scales above the ventral keel (not all-together rare) as well as being generally uni-colored. Closer examination perhaps reveals the "other" Striped corn mutation pattern, that is largely devoid of linear striping, randomly demonstrating instead, those "tweener" ovals between where dorso-lateral longitudinal striping should be for this mutation? . . .
