

SHOW & TELL

Two angles of the same 2014 hatchling corn snake. Not rare in Anery-type Bloodred mutants, the ventro-lateral white on neonates usually changes to gray with maturity. This degree of lateral white on non-Anery-type Bloodreds often changes to red with maturity, but since this is not an Anery, we'll have to wait to find out if it will stay white or change to the color that matches this morph. When this snake sheds next week, I'll find out if it's an Anery. BTW, if it turns out to be an Anery, it is the only one in three years of breeding its parents.
