

## Show & Tell

Though this individual has never been featured on my web site or SMR FaceBook page, some of you are surely saying, “looks like the others you’ve shown, Don”. While generally true that they share a basically consistent phenotype, they all seem to have different shades of color striping. This Striped mutant Trans-pecos Ratsnake (*Bogertophis subocularis*) is the homozygous form of the Striped gene mutation in this species. So far, all of them have utterly contiguous striping from neck to tail tip.
