

Show & Tell

Some of you are already aware that there have been few (if any) Striped Sunkissed-type mutants that actually demonstrate contiguous dorsal striping. These two Striped Honeys (Striped Sunkissed Caramels) exhibit typical pattern for this genetic compound. Another atypical pattern deviation in most Striped or Motley compound mutants is demonstration of some belly checkering, a feature that is usually seldom seen in Motleys of any other genetic persuasion. Most Motleys (and to my knowledge, ALL striped mutants), regardless of what other color or pattern mutations they possess, have no checkering on their bellies at all. These two hatchlings will be listed for sale in the coming weeks, after several feedings of unaltered frozen/thawed pinky mice.
