2017 13" female Pied-sided Bloodred corn snake for sale. She's currently eating frozen/thawed small pinky mice. Some of you are aware that the reason I named these Pied-sided (aka: p/s) instead of Pie-bald, Pied, or White-sided was because I knew that at least gene mutations are currently missing in the corn snake hobby are White-sided and Pied. Both have been demonstrated in many other serpent species, so it's a foregone conclusion that they WILL be demonstrated in corns. Not IF but WHEN. I didn't want to ruin either of those future discoveries by using the most applicable names Pied or White-sided, since the hallmark of this mutation is that the white is mostly relegated to the sides, and such white patches are generally disconnected and random in lateral zones. One name I toyed with when I first hatched these was "Red-sided" since regardless of how much and where the white patches are exhibited, they all had otherwise shockingly RED sides. The dorsal markings on toDAY's featured SOTD will greatly diffuse and will be deeply red at maturity. The lateral zones below the dorso-lateral demarcation line between longitudinal pattern zones will also be solidly red, except where the white is showing now. When I first named this morph I was tempted to call them Red-sided Bloodreds, but it was somewhat of a redundant name. Some pied-sided Bloodreds have no lateral white at all, but their resemblance to p/s Bloodreds is obvious, in the realm of the shockingly stark red sides. Her \$195.00 USD price includes to any of the lower-48 United States because she is what we consider a low-expression p/s Bloodred. Medium- and High-whites are considerably more rare in the hobby and consequently more expensive. . . . **SOLD**
