

Show & Tell

Two pictures of hatchlings from sister corns whose parents were het for Cinder, Sunkissed, and Lava. Pic 1 shows hatchlings from the first female's eggs that began hatching about a week ago. Pic 2 shows hatchlings from the second female's eggs that hatched July 16, 2018. Any educated guesses about which ones have what mutations will be welcomed. Especially if they're from ppl who have hatched some of these compound mutants. The success we get from pairing such multi-het corns is not only in getting them out of the eggs, but then, accurately deducing what the compound phenotypes are? **SECOND BROOD PIC . . .**
