

This snake is the F¹ generation product of pairing a Java corn with a Kastanie corn. The goal is to identify the inheritance of the Java morph, but it may be difficult since there is sometimes only a slight distinction between polygenetic, like-colored wild-type corns and one of the other mutations that look so much like wild-type corns (i.e. Kastanies). Hopefully, one more generation will help determine if the Java morph is actually a unique mutation, is a Kastanie or other existing mutation, or is simply a polygenic wild-type variant.
