

Each DAY at 11:00 am. ct (GMT - 5) we will post a different SMR snake being offered at a special price.

All snakes will be chosen for their rarity and/or unique beauty.

FREE U.S. SHIPPING for each Snake-of-the-Day.

.{simpleproduct:id=350}

toDAY's **SNAKE of the DAY** (Thu. Oct. 18, 2012)

Motley Het Honey

Male

d.o.h. 2010

33" long on October 18, 2012

\$175..00 shipped

Comments:

Het Honey (Sunkissed Caramel)

Motley (no aka)

Most Commonly Used Name: Motley

Mode of Genetic Inheritance: Recessive

Morph Type: Single Recessive Mutation

Eye Color: Black pupil & *body ground colored* iris

The first description of this corn snake pattern mutation was published by the late Dr. H. Bernard Bechtel in the 1980s. His breeding trials demonstrated the heritability of this mutation to be simple recessive. The distinguishing feature of those is belly checkering. Good Motleys have an orderly and contiguous pattern of

spots down the dorsum that represent spaces in what appears to be a continuous, wide stripe of color running from the neck tail-ward. The size, shape, location, organization, and number of circular pattern interruptions on the back define the grade of individuals, but until recently, the one pattern distinction we could rely upon was that of having no checkers on their belly. Lately, we're seeing Motleys with some black checkering, but it's random and sparse. I suspect that one DAY we'll see Motleys with quite a bit of belly checkering. In fact, certain genetic compounds of Motley have somewhat reliable belly markings (i.e. Sunglow Motley and Lavender Motley).

What to expect:

Thankfully, there is little change (if any) in the markings from hatchling to adult, but one characteristic impossible not to notice is that of diffusion of pattern and color throughout maturity. This essentially does change the pattern appearance, and it certainly does have interesting impacts on color compounds of Motley. Not unlike the "Diffused" mutation (aka: Bloodred) that diffuses color and pattern, Motleys virtually always enhance any other color or pattern mutation with which they have genetic union. Do not expect contiguous and orderly dorsal patterning, as Motleys with the best patterns are still in a minority in this morph. BTW, they are rare, but some non-mutant corns have dorsal pattern that is very similar to Motleys, but still a dependable distinguishing feature is the belly. If a *Motley-looking* corn has a busily checkered belly, it should not be a Motley mutant.

Important Note:

These images are not renderings of the actual animals being offered, (except for uniquely offered snakes found in the SURPLUS section of this web site). We do not provide pictures of individual hatchling snakes for sale, nor do we recommend that you ever choose a new pet based on an image of its neonatal form. Corns change so dramatically from hatchling to adult, they will NEVER have the same colors or contrasts throughout maturity. While most of the snakes we produce will mature to resemble the featured adult image(s) on our web site, unlike manufactured products that are respectively clones of each other, the nature of polygenic variation results in each animal being similar but not identical to others of its morph. The snake we select for you may not mature to be identical to the pictured examples, but will be chosen based on our experience of observing which neonates will mature to properly represent their respective morph. We take this responsibility very seriously, and therefore publish the guarantee that we will exchange your SMR snake if it does not mature to be like our advertised examples.
