

Specter (no aka) Most Commonly Used Name: Anery (*hobby abbreviation for Anerythristic*)

Mode of Genetic Inheritance: Recessive

Morph Type: Single Recessive Mutation

Eye Color: Black pupil & *body ground colored* iris (usually silver)

At this time Specters are thought to have a gene mutation that makes them distinctly unlike most Anery and Ghost corns, but no-one has yet identified an extra gene. Therefore, they are popularly considered a variant of Anery or Ghost.

What to expect:

Hatchling Specter corns look essentially like Classic Ghosts (Hypo Aneries). As they mature, they get a little pink in most of the ground color zones and even sometimes in the blotch zones, but not nearly as much as Heliconias that owe their remarkable pink to a red-modifying gene mutation.

Important Note:

These images are not renderings of the actual animals being offered, (except for uniquely offered snakes found in the SURPLUS section of this web site). We do not provide pictures of individual hatchling snakes for sale, nor do we recommend that you ever choose a new pet based on an image of its neonatal form. Corns change so dramatically from hatchling to adult, they will NEVER have the same colors or contrasts throughout maturity. While most of the snakes we produce will mature to resemble the featured adult image(s) on our web site, unlike manufactured products that are respectively clones of each other, the nature of polygenic variation results in each animal being similar but not identical to others of its morph. The snake we select for you may not mature to be identical to the pictured examples, but will be chosen based on our experience of observing which neonates will mature to properly represent their respective morph. We take this responsibility very seriously, and therefore publish the guarantee that we will exchange your SMR snake if it does not mature to be like our advertised examples.
