

Striped Hypo (no aka)

Most Commonly Used Name: Striped Hypo

Mode of Genetic Inheritance: Recessive

Morph Type: Mutation Compound (Stripe and Hypo)

Eye Color: Black pupil & *body ground colored* iris (some can be so hypomelanistic, their pupils can be gray to dark red).

The Stripe mutation has its usual enhanced impact in this double recessive mutation compound, but since the primary role of the Hypo mutation is in the realm of melanin reduction (not unlike that of the Stripe mutation), the effect is amplified in this aggregate. Striped Hypos are usually paler than either of their cousins, Hypo or Stripe. If not for the black pupils of the Striped Hypo in this image comparative, one would be tempted to say these two corns have virtually identical color.

What to expect:

Hatchlings often look like their non Hypo cousin, Striped Corns. Throughout maturity, the color and contrast in both pattern and ground zones diminishes to the point of most adult Striped Hypos being extremely faded in appearance. They are essentially lightened versions of the wild type color, since they are modified by both the Stripe and Hypo mutations. Striping can change in this morph, but always in reduction. They never gain striping or any other pattern, but some pattern can fade to the point of almost being impossible to see in their adult form.

Important Note:

The advertising images on our web site are representations of the average adult example of each morph. These images are not renderings of the actual animals being offered, (except for uniquely offered snakes found in the SURPLUS section of this web site). We do not provide pictures of individual hatchling snakes for sale, nor do we recommend that you ever choose a new pet based on an image of its neonatal form. Corns change so dramatically from hatchling to adult, they will NEVER have the same colors or contrasts throughout maturity.

While most of the snakes we produce will mature to resemble the featured adult image(s) on our web site, unlike manufactured products that are respectively clones of each other, the nature of polygenic variation results in each animal being similar but not identical to others of its morph. The snake we select for you may not mature to be identical to the pictured examples, but will be chosen based on our experience of observing which neonates will mature to properly represent their respective morph. We take this responsibility very seriously, and therefore publish the guarantee that we will exchange your SMR snake if it does not mature to be like our advertised examples.
